

Basic Models in TensorFlow

CS 20: TensorFlow for Deep Learning Research

Lecture 3

1/19/2017

Agenda

Review

Linear regression on birth/life data

Control Flow

tf.data

Optimizers, gradients

Logistic regression on MNIST

Loss functions

Review

Computation graph

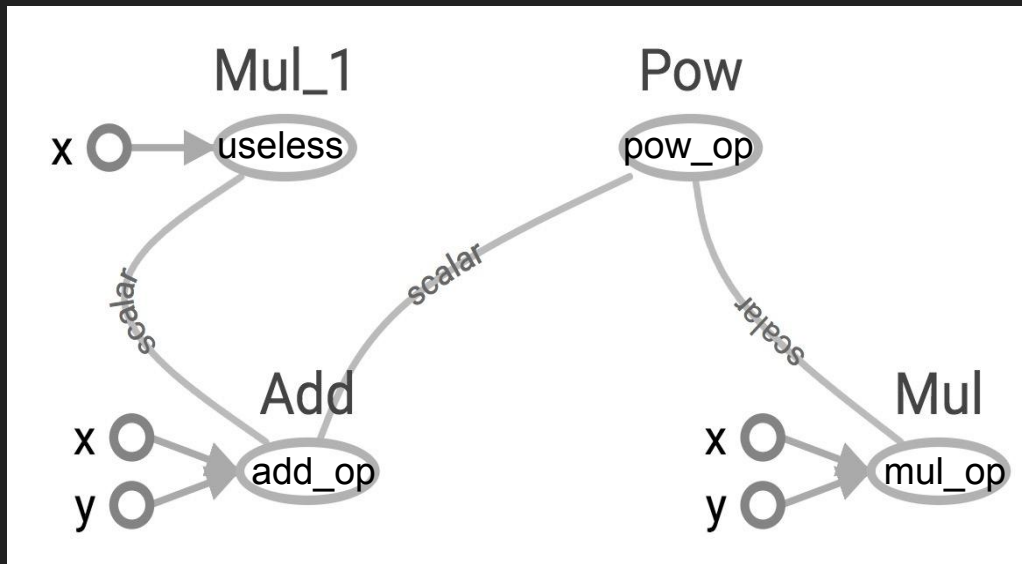

TensorFlow separates definition of computations from their execution

Phase 1: assemble a graph

Phase 2: use a session to execute operations in the graph.

TensorBoard

```
x = 2
y = 3
add_op = tf.add(x, y)
mul_op = tf.multiply(x, y)
useless = tf.multiply(x, add_op)
pow_op = tf.pow(add_op, mul_op)
with tf.Session() as sess:
    z = sess.run(pow_op)
```

Create a FileWriter object to write your graph to event files

tf.constant and tf.Variable

Constant values are stored in the graph definition

Sessions allocate memory to store variable values

tf.placeholder and feed_dict

Feed values into placeholders with a dictionary (feed_dict)

Easy to use but poor performance

Avoid lazy loading

1. Separate the assembling of graph and executing ops
2. Use Python attribute to ensure a function is only loaded the first time it's called

data/birth_life_2010.txt

Linear Regression in TensorFlow

Model the linear relationship between:

- dependent variable Y
- explanatory variables X

World Development Indicators dataset

X: birth rate
Y: life expectancy
190 countries

Want

Find a linear relationship between X and Y
to predict Y from X

Model

Inference: $Y_{\text{predicted}} = w * X + b$

Mean squared error: $E[(y - y_{\text{predicted}})^2]$

Interactive Coding

`data/birth_life_2010.txt`

Interactive Coding

`examples/03_linreg_starter.py`

Phase 1: Assemble our graph

Step 1: Read in data

I already did that for you

Step 2: Create placeholders for inputs and labels

```
tf.placeholder(dtype, shape=None, name=None)
```

Step 3: Create weight and bias

```
tf.get_variable(
```

```
    name,
```

```
    shape=None,
```

```
    dtype=None,
```

```
    initializer=None,
```

```
    ...
```

```
)
```

No need to specify shape if
using constant initializer

Step 4: Inference

$$Y_{\text{predicted}} = w * X + b$$

Step 5: Specify loss function

```
loss = tf.square(Y - Y_predicted, name='loss')
```

Step 6: Create optimizer

```
opt = tf.train.GradientDescentOptimizer(learning_rate=0.001)  
optimizer = opt.minimize(loss)
```

Phase 2: Train our model

Step 1: Initialize variables

Step 2: Run optimizer

(use a `feed_dict` to feed data into X and Y placeholders)

Write log files using a FileWriter

```
writer = tf.summary.FileWriter('./graphs/linear_reg', sess.graph)
```

See it on TensorBoard

Step 1: `$ python3 03_linreg_starter.py`

Step 2: `$ tensorboard --logdir='./graphs'`

TypeError?

```
TypeError: Fetch argument 841.0 has invalid type <class 'numpy.float32'>,  
must be a string or Tensor.
```

(Can not convert a float32 into a Tensor or Operation.)

TypeError

```
for i in range(50): # train the model 100 epochs
```

```
    total_loss = 0
```

```
    for x, y in data:
```

```
        _, loss = sess.run([optimizer, loss], feed_dict={X: x, Y:y}) # Can't fetch a numpy array
```

```
        total_loss += loss
```

TypeError

```
for i in range(50): # train the model 100 epochs

    total_loss = 0

    for x, y in data:

        _, loss_ = sess.run([optimizer, loss], feed_dict={X: x, Y:y})

        total_loss += loss_
```

Main Graph

Auxiliary Nodes

Plot the results with matplotlib

Step 1: Uncomment the plotting code at the end of your program

Step 2: Run it again

If run into problem of matplotlib in virtual environment, go to [GitHub/setup](#) and see the file possible setup problems

Huber loss

Robust to outliers

If the difference between the predicted value and the real value is small, square it

If it's large, take its absolute value

$$L_{\delta}(y, f(x)) = \begin{cases} \frac{1}{2}(y - f(x))^2 & \text{for } |y - f(x)| \leq \delta, \\ \delta |y - f(x)| - \frac{1}{2}\delta^2 & \text{otherwise.} \end{cases}$$

Implementing Huber loss

Can't write:

```
if y - y_predicted < delta:
```

$$L_{\delta}(y, f(x)) = \begin{cases} \frac{1}{2}(y - f(x))^2 & \text{for } |y - f(x)| \leq \delta, \\ \delta |y - f(x)| - \frac{1}{2}\delta^2 & \text{otherwise.} \end{cases}$$

Implementing Huber loss

```
tf.cond(pred, fn1, fn2, name=None)
```

$$L_{\delta}(y, f(x)) = \begin{cases} \frac{1}{2}(y - f(x))^2 & \text{for } |y - f(x)| \leq \delta, \\ \delta |y - f(x)| - \frac{1}{2}\delta^2 & \text{otherwise.} \end{cases}$$

Implementing Huber loss

```
tf.cond(pred, fn1, fn2, name=None)
```

```
def huber_loss(labels, predictions, delta=14.0):  
    residual = tf.abs(labels - predictions)  
    def f1(): return 0.5 * tf.square(residual)  
    def f2(): return delta * residual - 0.5 * tf.square(delta)  
    return tf.cond(residual < delta, f1, f2)
```

$$L_{\delta}(y, f(x)) = \begin{cases} \frac{1}{2}(y - f(x))^2 & \text{for } |y - f(x)| \leq \delta, \\ \delta |y - f(x)| - \frac{1}{2}\delta^2 & \text{otherwise.} \end{cases}$$

TF Control Flow

Control Flow Ops	<code>tf.group</code> , <code>tf.count_up_to</code> , <code>tf.cond</code> , <code>tf.case</code> , <code>tf.while_loop</code> , ...
Comparison Ops	<code>tf.equal</code> , <code>tf.not_equal</code> , <code>tf.less</code> , <code>tf.greater</code> , <code>tf.where</code> , ...
Logical Ops	<code>tf.logical_and</code> , <code>tf.logical_not</code> , <code>tf.logical_or</code> , <code>tf.logical_xor</code>
Debugging Ops	<code>tf.is_finite</code> , <code>tf.is_inf</code> , <code>tf.is_nan</code> , <code>tf.Assert</code> , <code>tf.Print</code> , ...

Since TF builds graph before computation, we have to specify all possible subgraphs beforehand. PyTorch's dynamic graphs and TF's eager execution help overcome this

tf.data

Placeholder

Pro: put the data processing outside TensorFlow, making it easy to do in Python

Cons: users often end up processing their data in a single thread and creating data bottleneck that slows execution down.

Placeholder

```
data, n_samples = utils.read_birth_life_data(DATA_FILE)

X = tf.placeholder(tf.float32, name='X')
Y = tf.placeholder(tf.float32, name='Y')
...
with tf.Session() as sess:
    ...
    # Step 8: train the model
    for i in range(100): # run 100 epochs
        for x, y in data:
            # Session runs train_op to minimize loss
            sess.run(optimizer, feed_dict={X: x, Y:y})
```

tf.data

Instead of doing inference with placeholders and feeding in data later, do inference directly with data

tf.data

tf.data.Dataset

tf.data.Iterator

Store data in `tf.data.Dataset`

- `tf.data.Dataset.from_tensor_slices((features, labels))`
- `tf.data.Dataset.from_generator(gen, output_types, output_shapes)`

Store data in `tf.data.Dataset`

```
tf.data.Dataset.from_tensor_slices((features, labels))
```

```
dataset = tf.data.Dataset.from_tensor_slices((data[:,0], data[:,1]))
```

Store data in tf.data.Dataset

```
tf.data.Dataset.from_tensor_slices((features, labels))

dataset = tf.data.Dataset.from_tensor_slices((data[:,0], data[:,1]))

print(dataset.output_types)      # >> (tf.float32, tf.float32)

print(dataset.output_shapes)     # >> (TensorShape([]), TensorShape([]))
```

Can also create Dataset from files

- `tf.data.TextLineDataset(filenamees)`
- `tf.data.FixedLengthRecordDataset(filenamees)`
- `tf.data.TFRecordDataset(filenamees)`

tf.data.Iterator

Create an iterator to iterate through samples in Dataset

tf.data.Iterator

- `iterator = dataset.make_one_shot_iterator()`
- `iterator = dataset.make_initializable_iterator()`

tf.data.Iterator

- `iterator = dataset.make_one_shot_iterator()`
Iterates through the dataset exactly once. No need to initialization.
- `iterator = dataset.make_initializable_iterator()`
Iterates through the dataset as many times as we want. Need to initialize with each epoch.

tf.data.Iterator

```
iterator = dataset.make_one_shot_iterator()
X, Y = iterator.get_next()          # X is the birth rate, Y is the life expectancy

with tf.Session() as sess:
    print(sess.run([X, Y]))          # >> [1.822, 74.82825]
    print(sess.run([X, Y]))          # >> [3.869, 70.81949]
    print(sess.run([X, Y]))          # >> [3.911, 72.15066]
```

tf.data.Iterator

```
iterator = dataset.make_initializable_iterator()
```

```
...
```

```
for i in range(100):  
    sess.run(iterator.initializer)  
    total_loss = 0  
    try:  
        while True:  
            sess.run([optimizer])  
    except tf.errors.OutOfRangeError:  
        pass
```

Handling data in TensorFlow

```
dataset = dataset.shuffle(1000)
```

```
dataset = dataset.repeat(100)
```

```
dataset = dataset.batch(128)
```

```
dataset = dataset.map(lambda x: tf.one_hot(x, 10))
```

```
# convert each elem of dataset to one_hot vector
```

Does tf.data really perform better?

Does tf.data really perform better?

With placeholder: 9.05271519 seconds

With tf.data: 6.12285947 seconds

Should we always use tf.data?

- For prototyping, feed dict can be faster and easier to write (pythonic)
- tf.data is tricky to use when you have complicated preprocessing or multiple data sources
- NLP data is normally just a sequence of integers. In this case, transferring the data over to GPU is pretty quick, so the speedup of tf.data isn't that large

**How does TensorFlow know what variables
to update?**

Optimizers

Optimizer

```
optimizer = tf.train.GradientDescentOptimizer(learning_rate=0.01).minimize(loss)  
_, l = sess.run([optimizer, loss], feed_dict={X: x, Y:y})
```

Optimizer

```
optimizer = tf.train.GradientDescentOptimizer(learning_rate=0.001).minimize(loss)  
_, l = sess.run([optimizer, loss], feed_dict={X: x, Y:y})
```

Session looks at all trainable variables that loss depends on and update them

Optimizer

Session looks at all trainable variables that optimizer depends on and update them

Trainable variables

```
tf.Variable(initial_value=None, trainable=True,...)
```

Specify if a variable should be trained or not
By default, all variables are trainable

List of optimizers in TF

`tf.train.GradientDescentOptimizer`

`tf.train.AdagradOptimizer`

`tf.train.MomentumOptimizer`

“Advanced” optimizers work better when tuned,
but are generally harder to tune

`tf.train.AdamOptimizer`

`tf.train.FtrlOptimizer`

`tf.train.RMSPropOptimizer`

...

Discussion question

- 1. How to know that our model is correct?**
- 2. How to improve our model?**

Assignment 1

Out tomorrow

Due 1/31

Optional Interactive Grading

Logistic Regression in TensorFlow

**Then he separated the
light from the darkness**

**The first logistic
regression model**

MNIST Database

Each image is a 28x28 array, flattened out to be a 1-d tensor of size 784

MNIST

X: image of a handwritten digit

Y: the digit value

Recognize the digit in the image

MNIST

X: image of a handwritten digit
Y: the digit value

Model

Inference: $Y_{\text{predicted}} = \text{softmax}(X * w + b)$

Cross entropy loss: $-\log(Y_{\text{predicted}})$

Process data

```
from tensorflow.examples.tutorials.mnist import input_data  
MNIST = input_data.read_data_sets('data/mnist', one_hot=True)
```

Process data

```
from tensorflow.examples.tutorials.mnist import input_data  
MNIST = input_data.read_data_sets('data/mnist', one_hot=True)
```

MNIST.train: 55,000 examples

MNIST.validation: 5,000 examples

MNIST.test: 10,000 examples

Process data

```
from tensorflow.examples.tutorials.mnist import input_data
MNIST = input_data.read_data_sets('data/mnist', one_hot=True)
```

```
MNIST.train: 55,000 examples
MNIST.validation: 5,000 examples
MNIST.test: 10,000 examples
```

No immediate way to convert Python generators
to `tf.data.Dataset`

Process data

```
mnist_folder = 'data/mnist'  
utils.download_mnist(mnist_folder)  
train, val, test = utils.read_mnist(mnist_folder, flatten=True)
```

Create datasets

```
mnist_folder = 'data/mnist'
utils.download_mnist(mnist_folder)
train, val, test = utils.read_mnist(mnist_folder, flatten=True)

train_data = tf.data.Dataset.from_tensor_slices(train)
train_data = train_data.shuffle(10000) # optional
test_data = tf.data.Dataset.from_tensor_slices(test)
```

Create iterator

```
mnist_folder = 'data/mnist'
utils.download_mnist(mnist_folder)
train, val, test = utils.read_mnist(mnist_folder, flatten=True)

train_data = tf.data.Dataset.from_tensor_slices(train)
train_data = train_data.shuffle(10000) # optional
test_data = tf.data.Dataset.from_tensor_slices(test)

iterator = train_data.make_initializable_iterator()
```

Create iterator

```
mnist_folder = 'data/mnist'
utils.download_mnist(mnist_folder)
train, val, test = utils.read_mnist(mnist_folder, flatten=True)

train_data = tf.data.Dataset.from_tensor_slices(train)
train_data = train_data.shuffle(10000) # optional
test_data = tf.data.Dataset.from_tensor_slices(test)

iterator = train_data.make_initializable_iterator()
img, label = iterator.get_next()
...
```

Problem?

Create iterator

```
mnist_folder = 'data/mnist'  
utils.download_mnist(mnist_folder)  
train, val, test = utils.read_mnist(mnist_folder, flatten=True)
```

```
train_data = tf.data.Dataset.from_tensor_slices(train)  
train_data = train_data.shuffle(10000) # optional  
test_data = tf.data.Dataset.from_tensor_slices(test)
```

```
iterator = train_data.make_initializable_iterator()  
img, label = iterator.get_next()  
...
```

>> Can only do inference with train_data.

>> Need to build another subgraph with another iterator for test_data!!!

Create iterator

```
mnist_folder = 'data/mnist'
utils.download_mnist(mnist_folder)
train, val, test = utils.read_mnist(mnist_folder, flatten=True)

train_data = tf.data.Dataset.from_tensor_slices(train)
train_data = train_data.shuffle(10000) # optional
test_data = tf.data.Dataset.from_tensor_slices(test)

iterator = tf.data.Iterator.from_structure(train_data.output_types,
                                           train_data.output_shapes)

img, label = iterator.get_next()

train_init = iterator.make_initializer(train_data) # initializer for train_data
test_init = iterator.make_initializer(test_data)   # initializer for train_data
```

Initialize iterator with the dataset you want

```
with tf.Session() as sess:
    ...
    for i in range(n_epochs):
        sess.run(train_init)                # use train_init during training loop
        try:
            while True:
                _, l = sess.run([optimizer, loss])
        except tf.errors.OutOfRangeError:
            pass
```

Initialize iterator with the dataset you want

```
with tf.Session() as sess:
    ...
    for i in range(n_epochs):
        sess.run(train_init)
        try:
            while True:
                _, l = sess.run([optimizer, loss])
        except tf.errors.OutOfRangeError:
            pass

    # test the model
    sess.run(test_init)  # use test_init during testing
    try:
        while True:
            sess.run(accuracy)
    except tf.errors.OutOfRangeError:
        pass
```

Phase 1: Assemble our graph

Step 1: Read in data

I already did that for you

Step 2: Create datasets and iterator

```
train_data = tf.data.Dataset.from_tensor_slices(train)
train_data = train_data.shuffle(10000) # optional
train_data = train_data.batch(batch_size)

test_data = tf.data.Dataset.from_tensor_slices(test)
test_data = test_data.batch(batch_size)
```

Step 2: Create datasets and iterator

```
iterator =  
tf.data.Iterator.from_structure(train_data.output_types,  
                               train_data.output_shapes)  
img, label = iterator.get_next()  
  
train_init = iterator.make_initializer(train_data)  
test_init = iterator.make_initializer(test_data)
```

Step 3: Create weights and biases

```
use tf.get_variable()
```

Step 4: Build model to predict Y

```
logits = tf.matmul(img, w) + b
```

We don't do softmax here, as we'll do softmax together with cross_entropy loss.
It's more efficient to compute gradients w.r.t. logits than w.r.t. softmax

Step 5: Specify loss function

```
entropy = tf.nn.softmax_cross_entropy_with_logits(labels=label,  
                                                  logits=logits)  
  
loss = tf.reduce_mean(entropy)
```

Step 6: Create optimizer

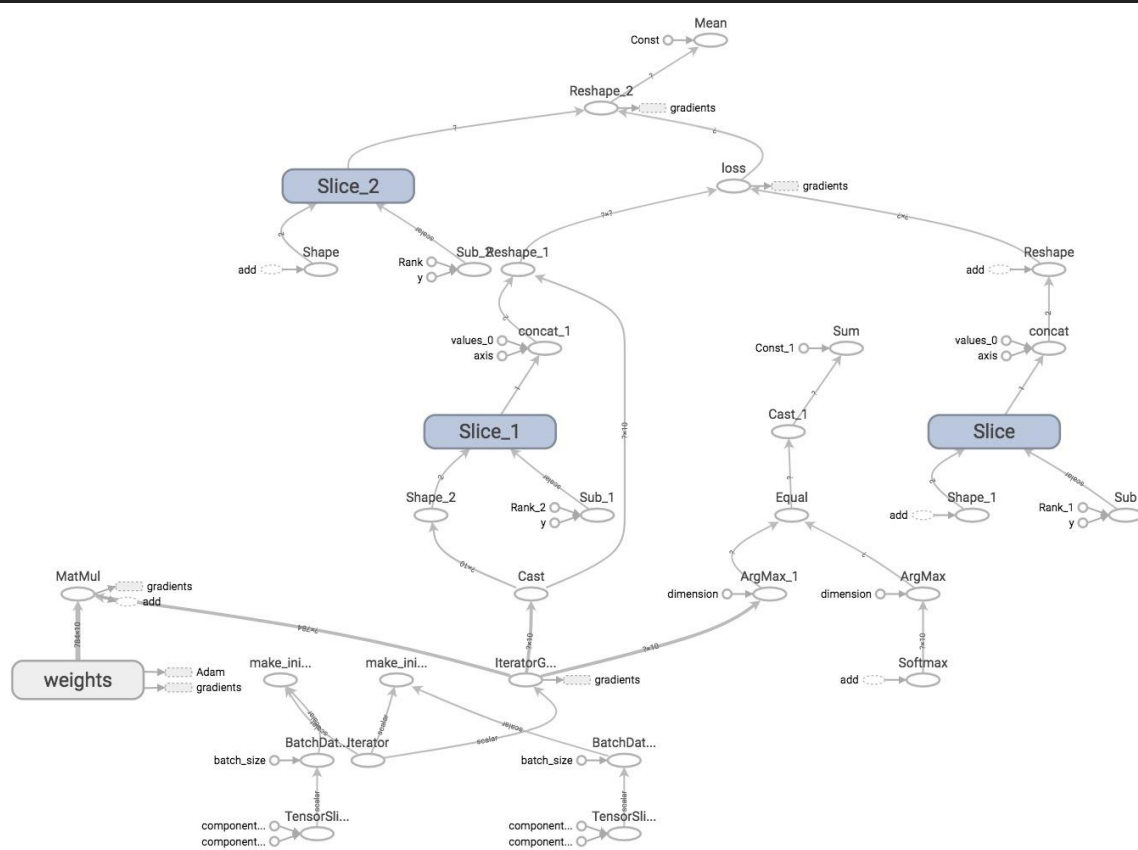

```
tf.train.AdamOptimizer(learning_rate=0.01).minimize(loss)
```

Phase 2: Train our model

Step 1: Initialize variables

Step 2: Run optimizer op

TensorBoard it
